### Abstract

The USACE ERDC is seeking innovative methods to use contaminated sediment beneficially and to include contaminated sediments in their 70/30 goal (70% beneficial use by 2030). While CDFs were originally built decades ago to confine contaminated sediments, much of the sediment more recently placed in CDFs is relatively clean, having been placed due to cost or other efficiencies in dredged material management. Clean sediment in CDFs can be used beneficially to realize more CDF capacity for contaminated material. This approach creates dual opportunities for beneficial sediment use: The first is to use clean material salvaged from existing CDFs, and the second is to use the expanded CDF capacity for contaminated sediment, which later will serve as a foundation for new lands.

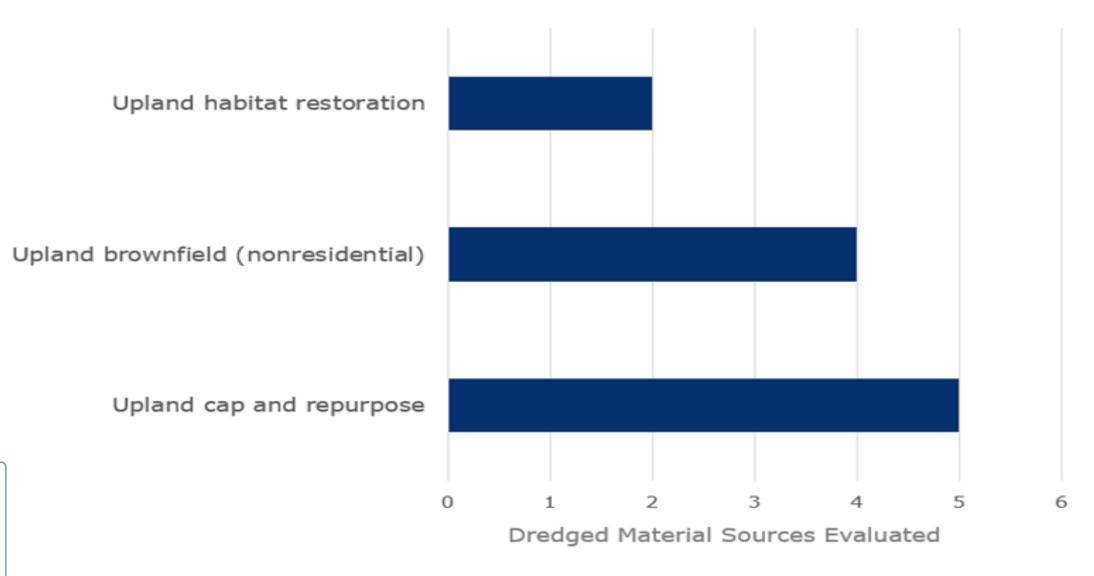

# **CDF Costs and Detroit District BU Opportunities**

BERM CONSTRUCTION

#### Average Great Lakes CDF Construction Costs (2023 USD) by type

#### No. of dredged material sources suited for potential BU alternatives

- Exiting: 29 acres poor quality habitat
- 20 yrs of CDF life: 29 acres managed CDF; poor quality habitat
- Post-closure: 25 acres forest habitat, 2 aces roadway, 2 acres grass with scattered trees

- Existing: 29 acres good condition forest habitat
- 20 yrs of CDF life: 29 acres managed CDF; poor quality habitat
- Post-closure: 29 acres forest habitat

- Existing: 15 acres contaminated wetlands
- Post remediation: 15 acres restored wetlands

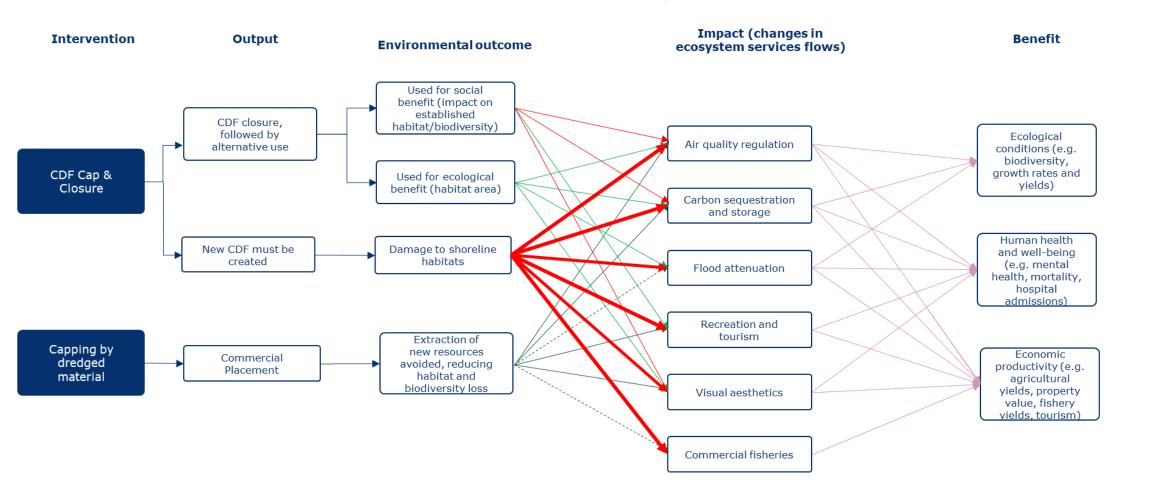

- Existing: 10 acres poor habitat (MGP site)
- Post remediation: 2 acres restored wetland swale, 3.5 acres restored forest, 1 acre managed lawn, 3.5 acres boat storage/parking

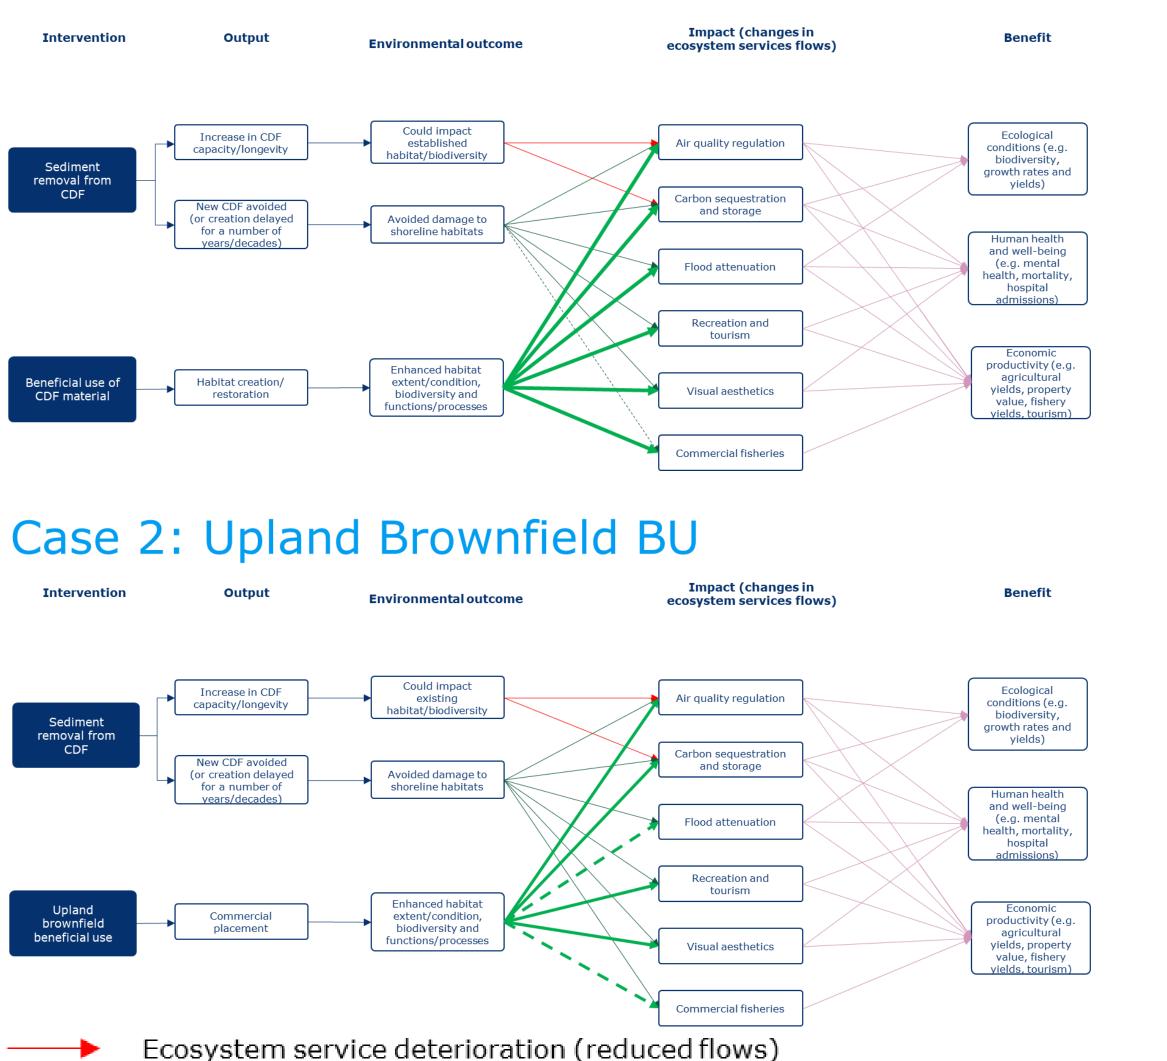

#### **Overview of Ecological Services**

## **Conceptual site models used to visualize CDF BU Opportunities and Costs**

Base Case CDF: No BU using CDF Material

## Case 1: Beneficial Use for New Habitat

Avoided loss in ES

Ecosystem service enhancement (increased flows) Potential ecosystem service flow (context-dependent)

Potential changes (+ and -) in benefit flows 

The thickness of the line denotes the anticipated magnitude of the flow

#### Scenario 1

 $\widehat{\Box}$ 

etland enhancement

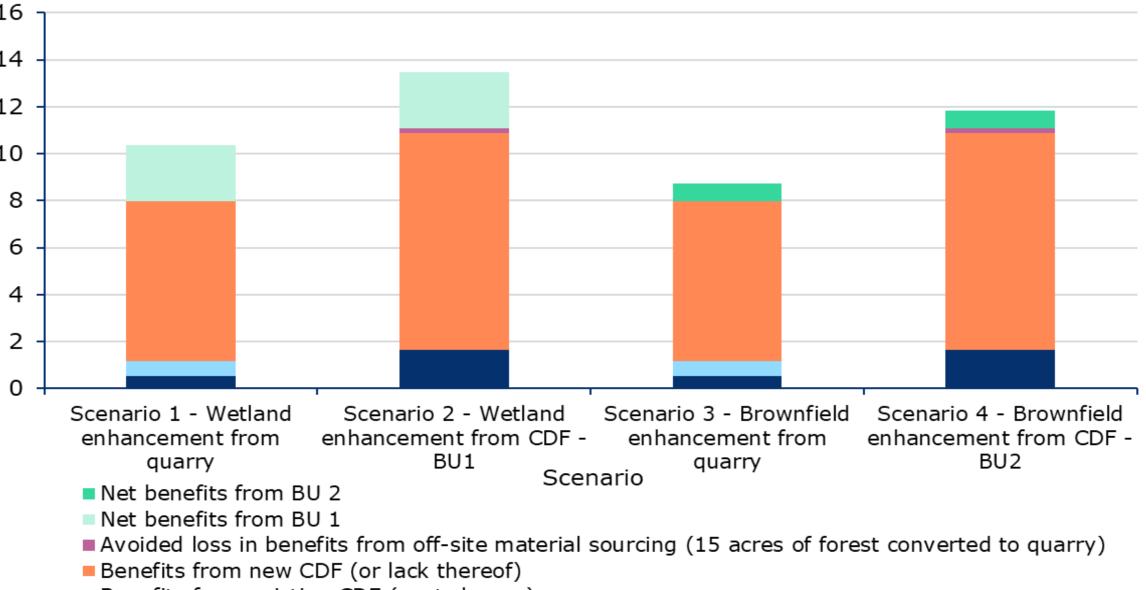

cenario 2

າ CDF (CDF BU1)

Scenario 3

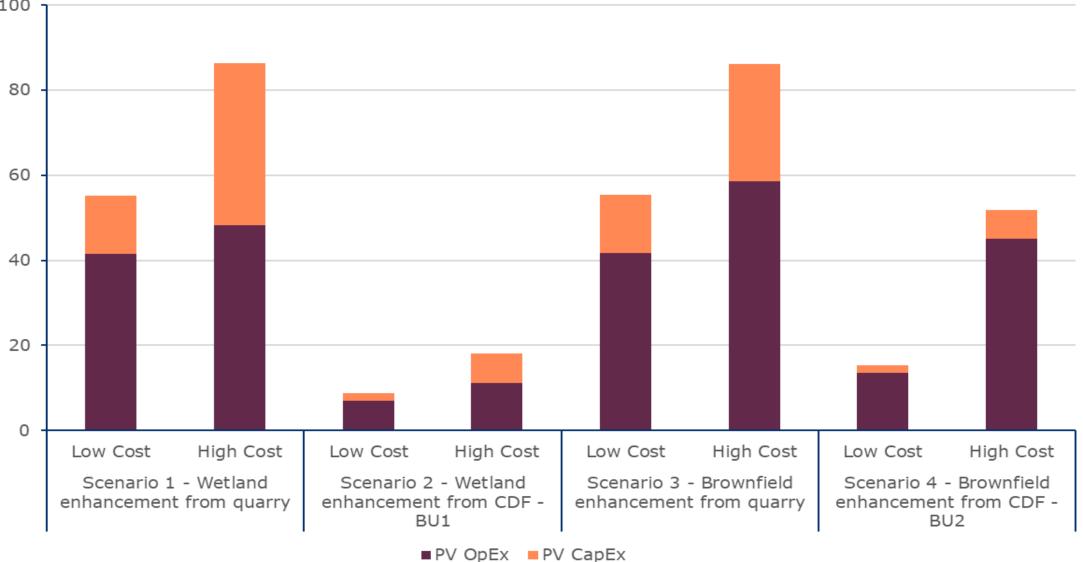

wnfield enhancement m quarry (BAU BU2) cenario 4

wnfield enhancem m CDF (CDF BU2)

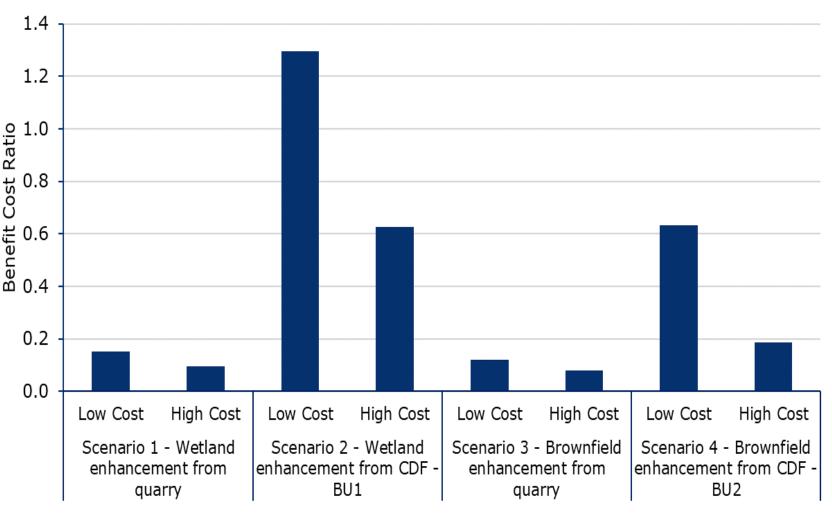

- nefits from existing CDF (post closure)
- Benefits from existing CDF (baseline)

#### **Present Value of Benefits**

#### **Present Value of Costs**

- The BCA Model shows the benefit of resourcing clean CDF material
- Use of CDF material for wetland uplift and brownfield enhancements was much more cost effective than resourcing borrow material (e.g., quarried material)
- Costs drove the BCRs far more than benefits
- Updated model can be a valuable tool for USACE to critically evaluate longevity of CDFs and the opportunity to beneficially use material at existing CDFs
